CSCI 480 Computer Graphics
Lecture 2

Basic Graphics Programming

Graphics Pipeline
OpenGL API
Primitives: Lines, Polygons
Attributes: Color
Example

January 12, 2011
Jernej Barbic
University of Southern California

[Angel Ch. 2]
What is OpenGL

- A low-level graphics API for 2D and 3D interactive graphics.
- Descendent of GL (from SGI)
OpenGL is cross-platform

- Same code works with little/no modifications

- Implementations:
  Windows, Mac: ships with the OS
  Linux: Mesa, a freeware implementation.

```c
#if defined(WIN32) || defined(__APPLE__)
    #include <GL/gl.h>
    #include <GL/glu.h>
    #include <GL/glut.h>
#elif defined(__APPLE__)
    #include <OpenGL/gl.h>
    #include <OpenGL/glu.h>
    #include <GLUT/glut.h>
#endif
```
How does OpenGL work

From the programmer’s point of view:

1. Specify geometric objects
2. Describe object properties
   • Color
   • How objects reflect light
3. Define how objects should be viewed
   • where is the camera
   • what type of camera

4. Move camera or objects around for animation
The result
OpenGL is a state machine

State variables: color, current viewing position, line width, material properties...

These variables (the state) then apply to every subsequent drawing command

They persist until set to new values by the programmer
OpenGL Library Organization

- GL (Graphics Library): core graphics capabilities
- GLU (OpenGL Utility Library): utilities on top of GL
- GLUT (OpenGL Utility Toolkit): input and windowing
Graphics Pipeline

Primitives+ material properties → Translate Rotate Scale → Is it visible on screen? → 3D to 2D → Convert to pixels → Shown on the screen (framebuffer)
Immediate-mode rendering

• Application generates stream of geometric primitives (polygons, lines)

• System draws each one into the framebuffer

• Entire scene redrawn anew every frame

• Contrast: off-line rendering (e.g., Pixar Renderman)
The pipeline is implemented by OpenGL, graphics driver and the graphics hardware.

OpenGL programmer does not need to implement the pipeline.

However, pipeline is reconfigurable if needed ➔ “shaders”
• Efficiently implementable in hardware (but not in software)

• Each stage can employ multiple specialized processors, working in parallel, busses between stages

• #processors per stage, bus bandwidths are fully tuned for typical graphics use

• Latency vs throughput
Vertices

- Vertices in **world coordinates**
- `void glVertex3f(GLfloat x, GLfloat y, GLfloat z)`
  - Vertex `(x, y, z)` sent down the pipeline
  - Function call returns
- Use GLtype for portability and consistency
- `glVertex{234}\{sfid\}[v](\textit{TYPE coords})`
Transformer

- Transformer in **world coordinates**
- Must be set **before** object is drawn!
  
  ```
  glRotatef(45.0, 0.0, 0.0, -1.0);
  glVertex2f(1.0, 0.0);
  ```

- **Complex [Angel Ch. 4]**
Clipper

- Mostly automatic (must set viewport)
Projector

- Complex transformation [Angel Ch. 5]

Orthographic

Perspective
Rasterizer

- Interesting algorithms [Angel Ch. 7]
- To window coordinates
- Antialiasing
Primitives

• Specified via vertices
• General schema
  
  ```
  glBegin(type);
  glVertex3f(x1, y1, z1);
  ...
  glVertex3f(xN, yN, zN);
  glEnd();
  ```

• *type* determines interpretation of vertices
• Can use `glVertex2f(x, y)` in 2D
Example: Draw Square Outline

• *Type = GL_LINE_LOOP*

```c
    glBegin(GL_LINE_LOOP);
    glVertex3f(0.0, 0.0, 0.0);
    glVertex3f(1.0, 0.0, 0.0);
    glVertex3f(1.0, 1.0, 0.0);
    glVertex3f(0.0, 1.0, 0.0);
    glEnd();
```

• Calls to other functions are allowed between `glBegin(type)` and `glEnd()`. 
Points and Line Segments

glBegin (GL_POINTS);
  glVertex3f(...);
  ...;
  glVertex3f(...);
  glEnd();

Draw points
Polygons

- Polygons enclose an area

- Rendering of area (fill) depends on attributes
- All vertices must be in one plane in 3D
Polygon Restrictions

- OpenGL Polygons must be **simple**
- OpenGL Polygons must be **convex**

(a) simple, but not convex

(b) non-simple

(c) convex
Why Polygon Restrictions?

- Non-convex and non-simple polygons are expensive to process and render
- Convexity and simplicity is expensive to test
- Behavior of OpenGL implementation on disallowed polygons is “undefined”
- Some tools in GLU for decomposing complex polygons (tessellation)
- Triangles are most efficient
Polygon Strips

- Efficiency in space and time
- Reduces visual artefacts

- Polygons have a front and a back, possibly with different attributes!
Attributes:
color, shading and reflection properties

• Part of the OpenGL state
• Set before primitives are drawn
• Remain in effect until changed!
Physics of Color

- Electromagnetic radiation
- Can see only tiny piece of the spectrum
Color Filters

• Eye can perceive only 3 basic colors
• Computer screens designed accordingly

Source: Vos & Walraven
Color Spaces

• RGB (Red, Green, Blue)
  – Convenient for display
  – Can be unintuitive (3 floats in OpenGL)

• HSV (Hue, Saturation, Value)
  – Hue: what color
  – Saturation: how far away from gray
  – Value: how bright

• Other formats for movies and printing
RGB vs HSV

Gimp Color Picker
Example: Drawing a shaded polygon

• Initialization: the “main” function

```c
int main(int argc, char** argv)
{
    glutInit(&argc, argv);
    glutInitDisplayMode (GLUT_DOUBLE | GLUT_RGB);
    glutInitWindowSize (500, 500);
    glutInitWindowPosition (100, 100);
    glutCreateWindow (argv[0]);
    init ();
    ...
```
GLUT Callbacks

- Window system independent interaction
- glutMainLoop processes events

```c
...
    glutDisplayFunc(display);
    glutReshapeFunc(reshape);
    glutKeyboardFunc(keyboard);
    glutMainLoop();
    return 0;
```
Initializing Attributes

• Separate in "init" function

```c
void init(void)
{
    glClearColor (0.0, 0.0, 0.0, 0.0);

    /* glShadeModel (GL_FLAT); */
    glShadeModel (GL_SMOOTH);
}
```
The Display Callback

• The routine where you render the object
• Install with glutDisplayFunc(display)

```c
void display(void)
{
    glClear (GL_COLOR_BUFFER_BIT); /* clear buffer */
    setupCamera(); /* set up the camera */
    triangle (); /* draw triangle */
    glutSwapBuffers (); /* force display */
}
```
Drawing

- In world coordinates; remember state!

```c
void triangle(void)
{
    glBegin (GL_TRIANGLES);
    glColor3f (1.0, 0.0, 0.0); /* red */
    glVertex2f (5.0, 5.0);
    glColor3f (0.0, 1.0, 0.0); /* green */
    glVertex2f (25.0, 5.0);
    glColor3f (0.0, 0.0, 1.0); /* blue */
    glVertex2f (5.0, 25.0);
    glEnd();
}
```
The Image

\texttt{glShadeModel(GL\_FLAT)}

- color of last vertex

\texttt{glShadeModel(GL\_SMOOTH)}

- each vertex separate color smoothly interpolated
Flat vs Smooth Shading

Flat Shading

Smooth Shading
Projection

- Mapping world to screen coordinates

void reshape(int w, int h)
{
    glViewport (0, 0, (GLsizei) w, (GLsizei) h);
    glMatrixMode (GL_PROJECTION);
    glLoadIdentity ();
    if (w <= h)
        gluOrtho2D (0.0, 30.0, 0.0, 30.0 * (GLfloat) h/(GLfloat) w);
    else
        gluOrtho2D (0.0, 30.0 * (GLfloat) w/(GLfloat) h, 0.0, 30.0);
    glMatrixMode(GL_MODELVIEW);
}
Orthographic Projection

- 2D and 3D versions
- `glOrtho2D(left, right, bottom, top)`
- In **world coordinates**!
Viewport

- Determines clipping in window coordinates
- `glViewport(x, y, w, h)`
Summary

1. A Graphics Pipeline
2. The OpenGL API
3. Primitives: vertices, lines, polygons
4. Attributes: color
5. Example: drawing a shaded triangle
