Hierarchical Models

Projections and Shadows
Hierarchical Models
[Angel Ch 5.10, 10.1-10.6]
Roadmap

• Last lecture: Viewing and projection
• Today:
  – Shadows via projections
  – Hierarchical models
• Next: Polygonal Meshes, Curves and Surfaces
• Goal: background for Assignment 2 (next week)
Importance of shadows

Source: UNC
Importance of shadows
Importance of shadows
Importance of shadows

Without shadows

With shadows

Source: UNC
Doom III

Reported to spend 50% of time rendering shadows!

Light sources

- Point light source
- Directional light source
- Area light source
Hard and soft shadows

Point light

Area light

Umbra

Penumbra

Hard shadow

Soft shadow

Source: UNC
Shadow Algorithms

- With visibility tests
  - Accurate yet expensive
  - Example: ray casting or ray tracing
  - Example: 2-pass z-buffer

- Without visibility tests ("fake" shadows)
  - Approximate and inexpensive
  - Using a model-view matrix "trick"

[Foley, Ch. 16.4.4] [RTR 6.12]
Shadows via Projection

- Assume light source at $[x_l, y_l, z_l]^T$
- Assume shadow on plane $y = 0$
- Viewing = shadow projection
  - Center of projection = light
  - Viewing plane = shadow plane
- View plane in front of object
- Shadow plane behind object
Shadow Projection Strategy

- Move light source to origin
- Apply appropriate projection matrix
- Move light source back
- Instance of general strategy: compose complex transformation from simpler ones!

\[
T = \begin{bmatrix}
1 & 0 & 0 & -x_l \\
0 & 1 & 0 & -y_l \\
0 & 0 & 1 & -z_l \\
0 & 0 & 0 & 1
\end{bmatrix}
\]
Derive Equation

- Now, light source at origin

\[
\begin{align*}
    y_p &= -y_l \\
    \frac{x_p}{x} &= \frac{y}{y_p} = \frac{y}{y} \\
    y_p &= -y_l \\
    z_p &= \frac{z}{y_p} = \frac{z}{y} \\
\end{align*}
\]

(see picture) (move light)
Light Source at Origin

• After translation, solve

\[
M \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} = w \begin{bmatrix} \frac{-xy_l}{y} \\ -y_l \\ -\frac{zy_l}{y} \\ 1 \end{bmatrix}
\]

• \( w \) can be chosen freely
• Use \( w = -y/y_l \)

\[
M \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} = \begin{bmatrix} x \\ y \\ z \\ -\frac{y}{y_l} \end{bmatrix}
\]
Shadow Projection Matrix

- Solution of previous equation

\[ M = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & -\frac{1}{y_t} & 0 & 0 & 0 \end{bmatrix} \]

- Total shadow projection matrix

\[ S = T^{-1}MT = \ldots \]
Implementation

• Recall column-major form

```c
GLfloat m[16] =
{1.0, 0.0, 0.0, 0.0,
  0.0, 1.0, 0.0, -1.0 / yl,
  0.0, 0.0, 1.0, 0.0,
  0.0, 0.0, 0.0, 0.0};
```

• $yl$ is light source height

• Assume drawPolygon(); draws object
Saving State

- Assume $x_l$, $y_l$, $z_l$ hold light coordinates

```c
glMatrixMode(GL_MODELVIEW);
drawPolygon();  /* draw normally */

glPushMatrix();  /* save current matrix */
glTranslatef($x_l$, $y_l$, $z_l$);  /* translate back */
glMultMatrixf(m);  /* project */
glTranslatef(-$x_l$, -$y_l$, -$z_l$);  /* move light to origin */
drawPolygon();  /* draw polygon again for shadow */
glPopMatrix();  /* restore original transformation */
...```
The Matrix and Attribute Stacks

• Mechanism to save and restore state
  – glPushMatrix();
  – glPopMatrix();

• Apply to current matrix

• Can also save current attribute values
  – Examples: color, lighting
  – glPushAttrib(GLbitfield mask);
  – glPopAttrib();
  – Mask determines which attributes are saved
**Drawing on a Surface**

- Shimmering (“z-buffer fighting”) when drawing shadow on surface
- Due to limited precision of depth buffer
- Solution: slightly displace either the surface or the shadow

`glPolygonOffset` in OpenGL
Drawing on a Surface

Or use general technique
1. Set depth buffer to read-only, draw surface
2. Set depth buffer to read-write, draw shadow
3. Set color buffer to read-only, draw surface again
4. Set color buffer to read-write
Outline

- Projections and Shadows
- Hierarchical Models
Hierarchical Models

• Many graphical objects are structured
• Exploit structure for
  – Efficient rendering
  – Example: tree leaves
  – Concise specification of model parameters
  – Example: joint angles
  – Physical realism
• Structure often naturally hierarchical
Instance Transformation

• Often we need several instances of an object
  – Wheels of a car
  – Arms or legs of a figure
  – Chess pieces
Instance Transformation

- Instances can be shared across space or time
- Write a function that renders the object in “standard” configuration
- Apply transformations to different instances
- Typical order: scaling, rotation, translation
Sample Instance Transformation

glMatrixMode(GL_MODELVIEW);	glLoadIdentity();	glTranslatef(...);	glRotatef(...);	glScalef(...);	gluCylinder(...);
Display Lists

• Sharing display commands
• Display lists are stored on the GPU
• May contain drawing commands and transfns.
• Initialization:

```c
GLuint torus = glGenLists(1);
glNewList(torus, GL_COMPILE);
Torus(8, 25);
glEndList();
```

• Use: `glCallList(torus);`
• Can share both within each frame, and across different frames in time
• Can be hierarchical: a display list may call another
Display Lists Caveats

- Store only results of expressions, not the expressions themselves
- Display lists cannot be changed or updated
- Effect of executing display list depends on current transformations and attributes
- Some implementation-dependent nesting limit
- They are deprecated:
  - for complex usage, use Vertex Buffer Object OpenGL extension instead
Drawing a Compound Object

• Example: simple “robot arm”

Base rotation $\theta$, arm angle $\phi$, joint angle $\psi$
Interleave Drawing & Transformation

- $h_1 =$ height of base, $h_2 =$ length of lower arm

```c
void drawRobot(GLfloat theta, GLfloat phi, GLfloat psi)
{
    glRotatef(theta, 0.0, 1.0, 0.0);
    drawBase();
    glTranslatef(0.0, h1, 0.0);
    glRotatef(phi, 0.0, 0.0, 1.0);
    drawLowerArm();
    glTranslatef(0.0, h2, 0.0);
    glRotatef(psi, 0.0, 0.0, 1.0);
    drawUpperArm();
}
```
Assessment of Interleaving

- Compact
- Correct “by construction”
- Efficient
- Inefficient alternative:
  - `glPushMatrix();`  `glPushMatrix();`  `...etc...`
  - `glRotatef(theta, ...);`  `glRotatef(theta, ...);`
  - `drawBase();`  `glTranslatef(...);`
  - `glPopMatrix();`  `glRotatef(phi, ...);`
  - `drawLowerArm();`  `glPopMatrix();`
- Count number of transformations
Hierarchical Objects and Animation

- Drawing functions are time-invariant
  
  ```
  drawBase(); drawLowerArm(); drawUpperArm();
  ```

- Can be easily stored in display list
- Change parameters of model with time
- Redraw when idle callback is invoked
A Bug to Watch

GLfloat theta = 0.0; ...; /* update in idle callback */
GLfloat phi = 0.0; ...; /* update in idle callback */
GLuint arm = glGenLists(1);
/* in init function */
glNewList(arm, GL_COMPILE);
    glRotatef(theta, 0.0, 1.0, 0.0);
drawBase();
...
drawUpperArm();
glEndList();
/* in display callback */
glCallList(arm);

What is wrong?
More Complex Objects

- Tree rather than linear structure
- Interleave along each branch
- Use push and pop to save state

![Diagram of a tree structure with nodes labeled Head, Left-upper arm, Right-upper arm, Left-upper leg, Right-upper leg, Left-lower arm, Right-lower arm, Left-lower leg, Right-lower leg. The diagram shows the interconnection of these nodes.]
Hierarchical Tree Traversal

- Order not necessarily fixed
- Example:

```c
void drawFigure()
{
    glPushMatrix(); /* save */
    drawTorso();
    glTranslatef(...); /* move head */
    glRotatef(...); /* rotate head */
    drawHead();
    glPopMatrix(); /* restore */
}
```
Using Tree Data Structures

- Can make tree form explicit in data structure

```c
typedef struct treenode
{
    GLfloat m[16];
    void (*f) ( );
    struct treenode *sibling;
    struct treenode *child;
} treenode;
```
Initializing Tree Data Structure

- Initializing transformation matrix for node
  
  ```
  treenode torso, head, ...;
  /* in init function */
  glLoadIdentity();
  glRotatef(...);
  glGetFloatv(GL_MODELVIEW_MATRIX, torso.m);
  ```

- Initializing pointers
  
  ```
  torso.f = drawTorso;
  torso.sibling = NULL;
  torso.child = &head;
  ```
Generic Traversal

• Recursive definition
  
  ```c
  void traverse (treenode *root)
  {
    if (root == NULL) return;
    glPushMatrix();
    glMultMatrixf(root->m);
    root->f();
    if (root->child != NULL) traverse(root->child);
    glPopMatrix();
    if (root->sibling != NULL) traverse(root->sibling);
  }
  ```

• C is really not the right language for this
Summary

• Projections and Shadows
• Hierarchical Models
Notes

• Wednesday – polygonal meshes, curves and surfaces
• Assignment 1 is due in one week
