The Graphics Pipeline, Revisited

• Must eliminate objects that are outside of viewing frustum
• Clipping: object space (eye coordinates)
• Scissoring: image space (pixels in frame buffer) – most often less efficient than clipping
• We will first discuss 2D clipping (for simplicity) – OpenGL uses 3D clipping

Clipping Against a Frustum

• General case of frustum (truncated pyramid)

• Clipping is tricky because of frustum shape

Perspective Normalization

• Solution:
  – Implement perspective projection by perspective normalization and orthographic projection
  – Perspective normalization is a homogeneous transformation

The Normalized Frustum

• OpenGL uses \(-1 \leq x,y,z \leq 1\) (others possible)
• Clip against resulting cube
• Clipping against arbitrary (programmer-specified) planes requires more general algorithms and is more expensive

The Viewport Transformation

• Transformation sequence again:
  1. Camera: From object coordinates to eye coords
  2. Perspective normalization: to clip coordinates
  3. Clipping
  4. Perspective division: to normalized device coords.
  5. Orthographic projection (setting \(z_p = 0\))
  6. Viewport transformation: to screen coordinates
• Viewport transformation can distort
  – Solution: pass the correct window aspect ratio to gluPerspective
Clipping

- General: 3D object against cube
- Simpler case:
  - In 2D: line against square or rectangle
  - Later: polygon clipping

Clipping Against Rectangle in 2D

- Line-segment clipping: modify endpoints of lines to lie within clipping rectangle

Clipping Against Rectangle in 2D

- The result (in red)

Clipping Against Rectangle in 2D

- Could calculate intersections of line segments with clipping rectangle
  - expensive, due to floating point multiplications and divisions
- Want to minimize the number of multiplications and divisions

y = kx + n
x = x_0
y = y_0

Several practical algorithms for clipping

- Main motivation:
  Avoid expensive line-rectangle intersections (which require floating point divisions)
- Cohen-Sutherland Clipping
- Liang-Barsky Clipping
- There are many more (but many only work in 2D)

Cohen-Sutherland Clipping

- Clipping rectangle is an intersection of 4 half-planes
- Encode results of four half-plane tests
- Generalizes to 3 dimensions (6 half-planes)
**Outcodes (Cohen-Sutherland)**

- Divide space into 9 regions
- 4-bit outcode determined by comparisons

- \( b_0: y > y_{\text{max}} \)
- \( b_1: y < y_{\text{min}} \)
- \( b_2: x > x_{\text{max}} \)
- \( b_3: x < x_{\text{min}} \)

\( o_1 = \text{outcode}(x_1, y_1) \)
\( o_2 = \text{outcode}(x_2, y_2) \)

**Cases for Outcodes**

- Outcomes: accept, reject, subdivide

- \( o_1 = o_2 = 0000: \) accept entire segment
- \( o_1 \& o_2 \neq 0000: \) reject entire segment
- \( o_1 = 0000, o_2 = 0000: \) subdivide
- \( o_1 \neq 0000, o_2 = 0000: \) subdivide
- \( o_1 \& o_2 = 0000: \) subdivide

**Cohen-Sutherland Subdivision**

- Pick outside endpoint \( (o \neq 0000) \)
- Pick a crossed edge \( (o = b_0 b_1 b_2 b_3 \text{ and } b_k = 0) \)
- Compute intersection of this line and this edge
- Replace endpoint with intersection point
- Restart with new line segment
  - Outcodes of second point are unchanged
- This algorithms converges

**Liang-Barsky Clipping**

- Start with parametric form for a line

\[
\begin{align*}
  p(\alpha) &= (1 - \alpha)p_1 + \alpha p_2, \quad 0 \leq \alpha \leq 1 \\
  x(\alpha) &= (1 - \alpha)x_1 + \alpha x_2 \\
  y(\alpha) &= (1 - \alpha)y_1 + \alpha y_2
\end{align*}
\]

**Ordering of intersection points**

- Order the intersection points
- Figure (a): \( 1 > \alpha_4 > \alpha_3 > \alpha_2 > \alpha_1 > 0 \)
- Figure (b): \( 1 > \alpha_4 > \alpha_2 > \alpha_3 > \alpha_1 > 0 \)
Liang-Barsky Idea

- It is possible to clip already if one knows the order of the four intersection points!
- Even if the actual intersections were not computed!
- Can enumerate all ordering cases

\[
\begin{align*}
\alpha_3 &= \frac{y_{\text{max}} - y_1}{y_2 - y_1} \\
\alpha_2 &= \frac{x_{\text{min}} - x_1}{x_2 - x_1}
\end{align*}
\]

Liang-Barsky efficiency improvements

- Efficiency improvement 1:
  - Compute intersections one by one
  - Often can reject before all four are computed
- Efficiency improvement 2:
  - Equations for \( \alpha_3, \alpha_2 \)
  \[
  y_{\text{max}} = (1 - \alpha_3)y_1 + \alpha_3y_2 \\
x_{\text{min}} = (1 - \alpha_2)x_1 + \alpha_2x_2
  \]

Line-Segment Clipping Assessment

- Cohen-Sutherland
  - Works well if many lines can be rejected early
  - Recursive structure (multiple subdivisions) is a drawback
- Liang-Barsky
  - Avoids recursive calls
  - Many cases to consider (tedious, but not expensive)

Outline

- Line-Segment Clipping
  - Cohen-Sutherland
  - Liang-Barsky
- Polygon Clipping
  - Sutherland-Hodgeman
- Clipping in Three Dimensions

Polygon Clipping

- Convert a polygon into one or more polygons
- Their union is intersection with clip window
- Alternatively, we can first tesselate concave polygons (OpenGL supported)

Concave Polygons

- Approach 1: clip, and then join pieces to a single polygon
  - Often difficult to manage
- Approach 2: tesselate and clip triangles
  - This is the common solution
Sutherland-Hodgeman (part 1)

- Subproblem:
  - Input: polygon (vertex list) and single clip plane
  - Output: new (clipped) polygon (vertex list)
- Apply once for each clip plane
  - 4 in two dimensions
  - 6 in three dimensions
  - Can arrange in pipeline

Sutherland-Hodgeman (part 2)

- To clip vertex list (polygon) against a half-plane:
  - Test first vertex. Output if inside, otherwise skip.
  - Then loop through list, testing transitions
    - In-to-in: output vertex
    - In-to-out: output intersection
    - out-to-in: output intersection and vertex
    - out-to-out: no output
  - Will output clipped polygon as vertex list
- May need some cleanup in concave case
- Can combine with Liang-Barsky idea

Other Cases and Optimizations

- Curves and surfaces
  - Do it analytically if possible
  - Otherwise, approximate curves / surfaces by lines and polygons
- Bounding boxes
  - Easy to calculate and maintain
  - Sometimes big savings

Outline

- Line-Segment Clipping
  - Cohen-Sutherland
  - Liang-Barsky
- Polygon Clipping
  - Sutherland-Hodgeman
- Clipping in Three Dimensions

Clipping Against Cube

- Derived from earlier algorithms
- Can allow right parallelepiped

Cohen-Sutherland in 3D

- Use 6 bits in outcode
  - \( b_4: z > z_{\text{max}} \)
  - \( b_5: z < z_{\text{min}} \)
- Other calculations as before
Liang-Barsky in 3D

- Add equation \( z(\alpha) = (1-\alpha)z_1 + \alpha z_2 \)
- Solve, for \( p_0 \) in plane and normal \( n \):
  \[
p(\alpha) = (1-\alpha)p_1 + \alpha p_2 \quad n \cdot (p(\alpha) - p_0) = 0
  \]
- Yields
  \[
  \alpha = \frac{n \cdot (p_0 - p_1)}{n \cdot (p_2 - p_1)}
  \]
- Optimizations as for Liang-Barsky in 2D

Summary: Clipping

- Clipping line segments to rectangle or cube
  - Avoid expensive multiplications and divisions
  - Cohen-Sutherland or Liang-Barsky
- Polygon clipping
  - Sutherland-Hodgeman pipeline
- Clipping in 3D
  - essentially extensions of 2D algorithms
